

Algorithmic Complexity

Algorithmic Complexity

"**Algorithmic Complexity**", also called "**Running Time**" or "**Order of Growth**", refers to the number of steps a program takes as a function of the size of its inputs. In this class, we will assume the function only has one input, which we will say has length n .

Algorithmic Complexity

Notes on Notation:

Algorithmic complexity is usually expressed in 1 of 2 ways. The first is the way used in lecture - "logarithmic", "linear", etc. The other is called **Big-O notation**. This is a more mathematical way of expressing running time, and looks more like a function. For example, a "linear" running time can also be expressed as $O(n)$. Similarly, a "logarithmic" running time can be expressed as $O(\log n)$.

Algorithmic Complexity

Here is a list of some common running times:

Constant	$O(1)$
Logarithmic	$O(\log n)$
Linear	$O(n)$
Quadratic	$O(n^2)$
Cubic	$O(n^3)$
Exponential	$O(2^n)$

We will talk about each briefly.

Constant-Time Algorithms - $O(1)$

A **constant-time algorithm** is one that takes the same amount of time, regardless of its input. Here are some examples:

- Given two numbers*, report the sum
- Given a list, report the first element
- Given a list of numbers*, report the result of adding the first element to itself 1,000,000 times

Why is the last example still constant time?

*Here, we are referring to numbers of a set maximum size (i.e. 32-bit numbers, 64-bit numbers, etc.)

Logarithmic-Time Algorithm - $O(\log n)$

A **logarithmic-time algorithm** is one that requires a number of steps proportional to the $\log(n)$. In most cases, we use 2 as the base of the log, but it doesn't matter which base because we ignore constants. Because we use the base 2, we can rephrase this in the following way: *every time the **size of the input doubles**, our algorithm performs **one more step***. Examples:

- Binary search
- Searching a tree data structure (we'll see what this is later)

Linear-Time Algorithms - $O(n)$

A **linear-time algorithm** is one that takes a number of steps directly proportional to the size of the input. In other words, if the size of the **input doubles**, the number of **steps doubles**. Examples:

- Given a list of words, say each item of a list
- Given a list of numbers, add each pair of numbers together (item 1 + item 2, item 3 + item 4, etc.)
- Given a list of numbers, multiply every 3rd number by 2

Again, why is the last algorithm still linear?

Quadratic-Time Algorithms - $O(n^2)$

A **quadratic-time algorithm** is one that takes a number of steps proportional to n^2 . That is, if the size of the **input doubles**, the number of **steps quadruples**. A typical pattern of quadratic-time algorithms is performing a linear-time operation on each item of the input (n steps per item * n items = n^2 steps). Examples:

- Compare each item of a list against all the other items in the list
- Fill in a n -by- n game board

Cubic-Time Algorithms - $O(n^3)$

A **cubic-time algorithm** is one that takes a number of steps proportional to n^3 . In other words, if the **input doubles**, the number of **steps is multiplied by 8**. Similarly to the quadratic case, this could be the result of applying an n^2 algorithm to n items, or applying a linear algorithm to n^2 items. Examples:

- Fill in a 3D board (or environment)
- For each object in a list, construct an n -by- n bitmap drawing of the object

Exponential-Time Algorithms - $O(2^n)$

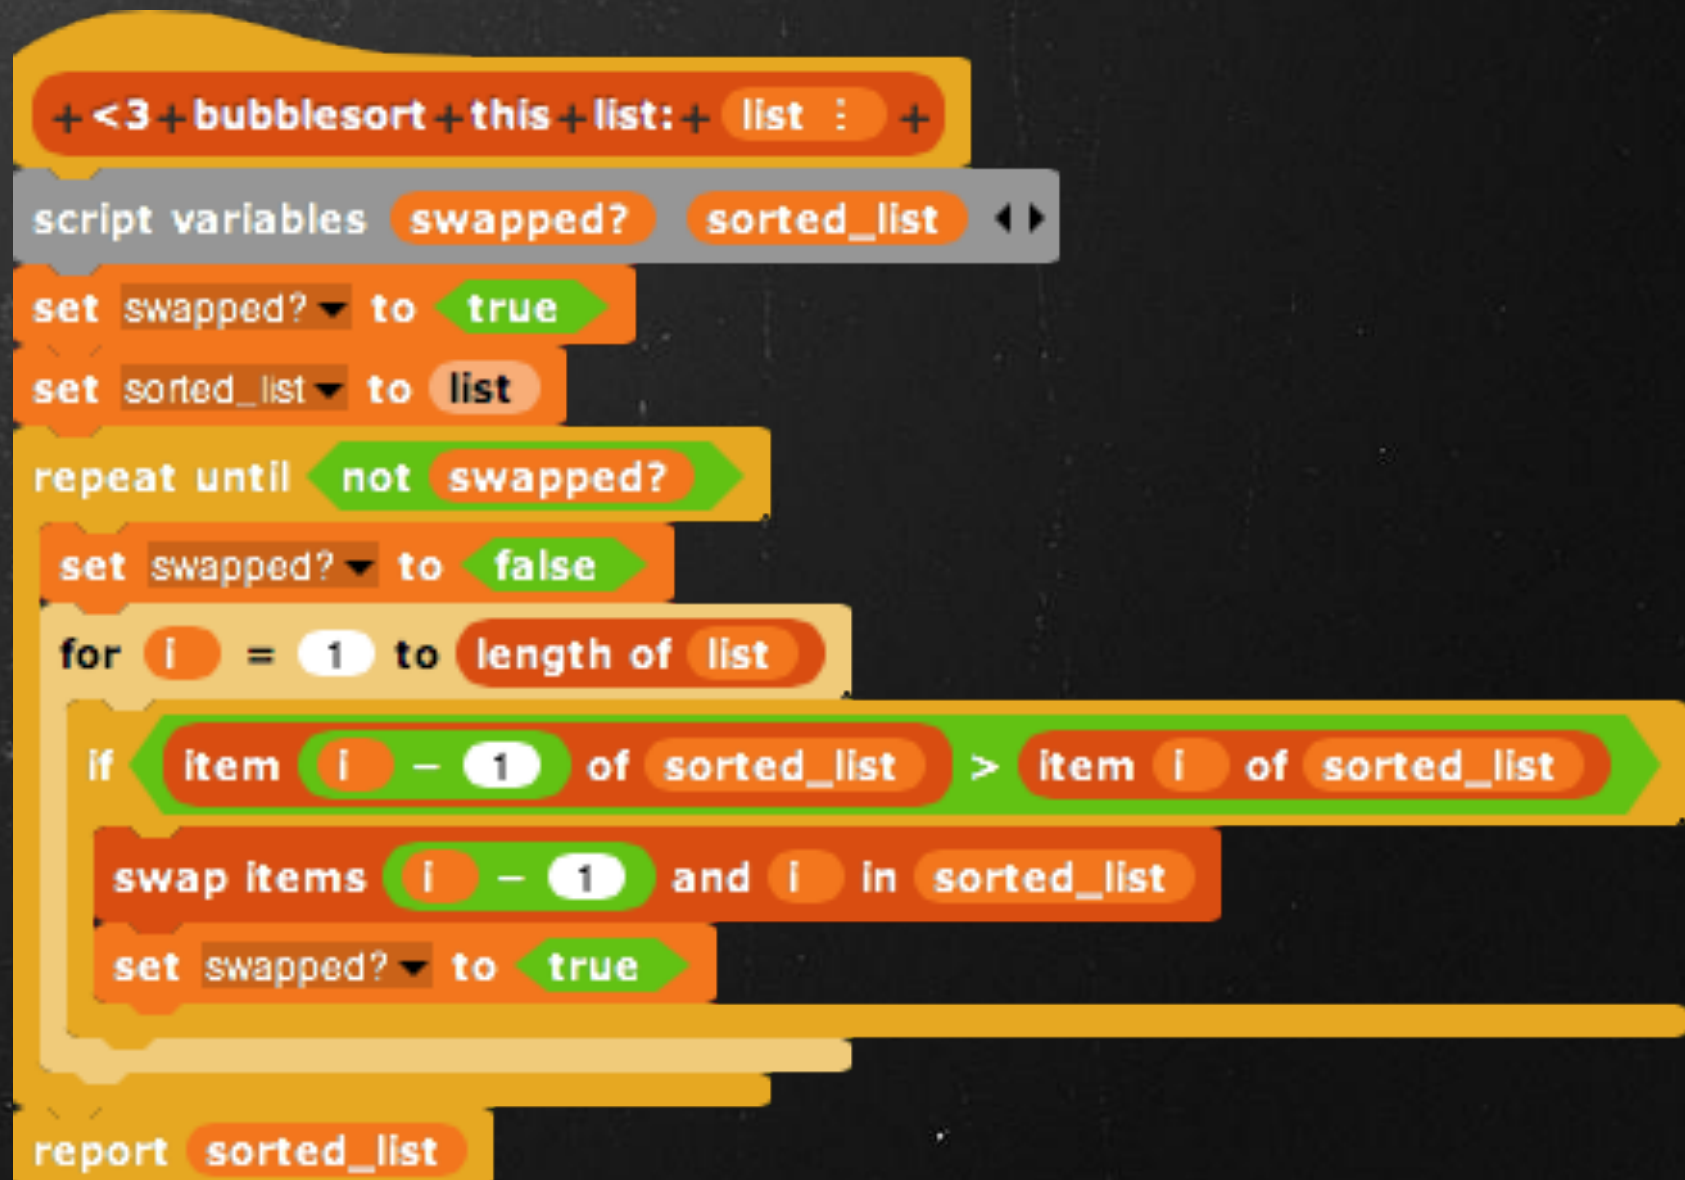

An **exponential-time algorithm** is one that takes time proportional to 2^n . In other words, if the size of the **input increases by one**, the number of **steps doubles**. Note that logarithms and exponents are inverses of each other. Algorithms in this category are often considered too slow to be practical, especially if the input is typically large. Examples:

- Given a number n , generate a list of every n -bit binary number

What is the runtime?

What is the runtime?

```
+<3+ bubblesort + this + list: + list : +
script variables swapped? sorted_list <>
set swapped? to true
set sorted_list to list
repeat until not swapped?
  set swapped? to false
  for i = 1 to length of list
    if item i - 1 of sorted_list > item i of sorted_list
      swap items i - 1 and i in sorted_list
      set swapped? to true
  report sorted_list
```

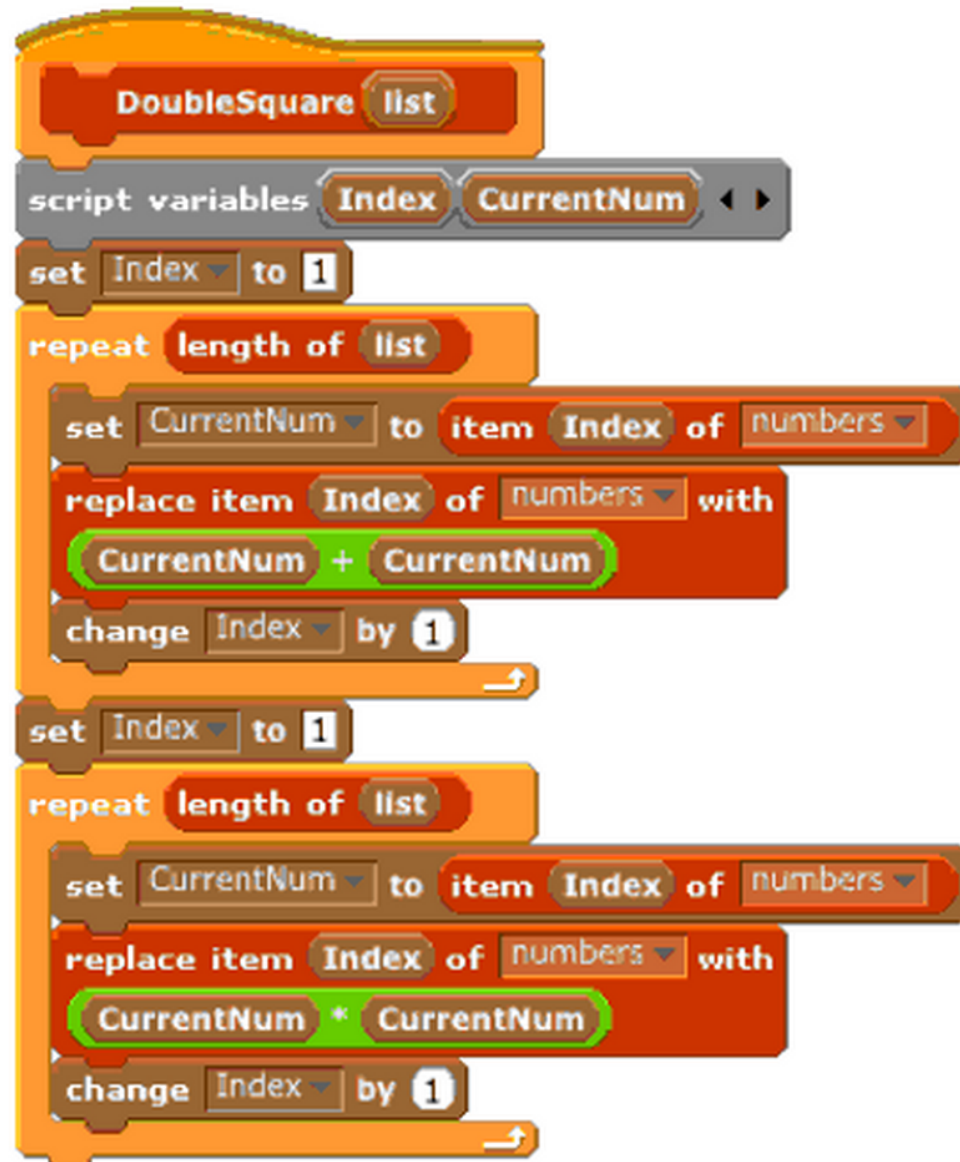

The image shows a Scratch script for a bubble sort algorithm. The script is written in a block-based language and includes the following steps:

- Define script variables: `swapped?` and `sorted_list`.
- Set `swapped?` to `true`.
- Set `sorted_list` to `list`.
- Repeat until `not swapped?`:
 - Set `swapped?` to `false`.
 - For `i = 1` to `length of list`:
 - If `item i - 1 of sorted_list > item i of sorted_list`:
 - Swap items `i - 1` and `i` in `sorted_list`.
 - Set `swapped?` to `true`.
- Report `sorted_list`.

What is the runtime?

What is the runtime?

What is the runtime?

What is the runtime?

Take a look at the code to the right. What is it doing? What is its running time? Hint: it drew the picture below.

```
do cooler stuff with list
clear
set pen size to 10
set size to 25 %
script variables i j
go to x: -200 y: 150
pen down
set j to 1
repeat length of list
  set i to 1
  repeat length of list
    set pen color to item i of list + item j of list
    move round 400 / length of list steps
    change i by 1
  pen up
  change y by -1 * round 300 / length of list
  set x to -200
  pen down
  change j by 1
pen up
```
